1 PROBLEM 1

For the following system:

$$\begin{aligned} \dot{x}_1 &= -x_1^3 + x_2 \\ \dot{x}_2 &= x_1 - x_2^3 \end{aligned}$$

a) find three equilibria

Equilibria are at x^* where $\dot{x}^* = 0$. Therefore

$$\begin{aligned} 0 &= -x_1^3 + x_2 \\ 0 &= x_1 - x_2^3 \end{aligned}$$

This is true at:

$$x_1^* = \begin{bmatrix} 0 & 0 \end{bmatrix}^T \tag{1.1}$$

$$x_2^* = \begin{bmatrix} 1 & 1 \end{bmatrix}^T \tag{1.2}$$

$$x_3^* = \begin{bmatrix} -1 & -1 \end{bmatrix}^T \tag{1.3}$$

$$\tag{1.4}$$

b) Find the type of each equilibrium

$$x = x^* + \delta x$$

$$\dot{x} = \dot{x}^* + \delta \dot{x} = \left. \frac{\partial f}{\partial x} \right|_{x^*}$$

$$A = \begin{bmatrix} \frac{\partial f_1}{\partial x_1} & \frac{\partial f_1}{\partial x_2} \\ \frac{\partial f_2}{\partial x_1} & \frac{\partial f_2}{\partial x_2} \end{bmatrix} = \begin{bmatrix} -3x_1^2 & 1 \\ 1 & -3x_2^2 \end{bmatrix}$$

By evaluating matrix A at each equilibrium and finding it's eigenvalues, we can determine the type of equilibrium.

Equilibrium 1:

$$A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \quad (1.5)$$

$$\lambda = -1, 1 \Rightarrow \textit{saddle point} \quad (1.6)$$

Equilibrium 2:

$$A = \begin{bmatrix} -3 & 1 \\ 1 & -3 \end{bmatrix} \quad (1.7)$$

$$\lambda = -4, -2 \Rightarrow \textit{stable node} \quad (1.8)$$

Equilibrium 3:

$$A = \begin{bmatrix} -3 & 1 \\ 1 & -3 \end{bmatrix} \quad (1.9)$$

$$\lambda = -4, -2 \Rightarrow \textit{stable node} \quad (1.10)$$

2 PROBLEM 2

a) Find the equilibrium of the system: The equilibrium is at $x^* = [0 \ 0]^T$. This makes

$$\begin{aligned}\dot{x}_1 &= (1+0)(0-0) = 0 \\ \dot{x}_2 &= 0(1+0) = 0\end{aligned}$$

b) Make the strongest possible statement about the stability of the system using the given Lyapunov equation:

$$V(x_1, x_2) = \frac{x_1^2}{1+x_1^2} + \frac{x_2^2}{1+x_2^2} \quad (2.1)$$

V is positive definite because $V = 0$ only if $x = [0 \ 0]^T$.

$$\dot{V} = \frac{\partial V}{\partial x_1} \dot{x}_1 + \frac{\partial V}{\partial x_2} \dot{x}_2 \quad (2.2)$$

$$= \frac{(1+x_1^2)2x_1 - x_1^2(2x_1)}{(1+x_1^2)^2}(1+x_1^2)^2(-x_1-x_2) + \frac{(1+x_2^2)2x_2 - x_2^2(2x_2)}{(1+x_2^2)^2}x_1(1+x_1^2)^2 \quad (2.3)$$

$$= (2x_1 + 2x_1^3 - 2x_1^3)(-x_1 - x_2) + (2x_2 + 2x_2^3 - 2x_2^3)x_1 \quad (2.4)$$

$$= -2x_1^2 \quad (2.5)$$

Therefore \dot{V} is negative semi-definite, and the equilibrium is stable. We can use LaSalle's theorem to show that the equilibrium of this time-invariant system is asymptotically stable.

Let $S = \{x \in D | x_1 = 0\}$. Let x_1, x_2 be solutions staying in S . $V = \dot{V} = 0$ implies that $x_1 = 0$, and therefore $\dot{x}_1 = 0$. This leaves the equation for V as:

$$0 = \frac{x_2^2}{1+x_2^2} \quad (2.6)$$

The only solution for which this is true is $x_2 = 0$. By LaSalle's theorem, the equilibrium is asymptotically stable.

The above is true for $x \in D = \mathbb{R}^2$, and additionally V is radially unbounded. Therefore, the equilibrium is globally asymptotically stable.

3 PROBLEM 3

a) Show that the given Lyapunov equation is positive definite (p.d.).

$$V(x_1, x_2) = \frac{3}{2}x_1^2 - x_1x_2 + x_2^2 \quad (3.1)$$

$$= \begin{bmatrix} x_1 & x_2 \end{bmatrix} \mathbf{P} \begin{bmatrix} x_1 & x_2 \end{bmatrix}^T \quad (3.2)$$

$$= \begin{bmatrix} x_1 & x_2 \end{bmatrix} \begin{bmatrix} 3/2 & -2 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} x_1 & x_2 \end{bmatrix}^T \quad (3.3)$$

V is p.d. if \mathbf{P} is p.d. Matrix \mathbf{P} is p.d. if the eigenvalues of $[\mathbf{P} + \mathbf{P}^T]/2 > 0$, or equivalently if the determinant of each leading principle minor is positive.

$$[P + P^T]/2 = Q = \begin{bmatrix} 3/2 & -\frac{1}{2} \\ -\frac{1}{2} & 1 \end{bmatrix} \quad (3.4)$$

Both leading principle minors of \mathbf{Q} are positive, and therefore V is positive definite.

b) Show that the equilibrium is asymptotically stable:

$$\dot{V} = \frac{\partial V}{\partial x_1} \dot{x}_1 + \frac{\partial V}{\partial x_2} \dot{x}_2 \quad (3.5)$$

$$= (3x_1 - x_2)(-x_2) + (2x_2 - x_1)((x_1^2 - 1)x_2 + x_1) \quad (3.6)$$

$$= -x_1^2 - x_2^2 + 2x_1^2x_2^2 - x_1^3x_2 \quad (3.7)$$

$$= -x_1^2(1 + x_1x_2) - x_2^2(1 - 2x_1^2) \quad (3.8)$$

In the domain $D = \{x_1, x_2 \in \mathbb{R} \mid 1 + x_1x_2 > 0, x_1^2 < \frac{1}{2}\}$, \dot{V} is negative definite, and therefore the equilibrium is asymptotically stable.

c) For a constant c , the sublevel set Ω_c of V is described by an ellipse. This ellipse can be found from the equation of V . The equation of an ellipse is given by

$$0 = Ax^2 + Bxy + Cy^2 + Dx + Ey + F \quad (3.9)$$

where the coefficients are calculated as functions of the semi-major (a) and semi-minor (b) axes, and angle (θ) of the semi-major axis. In this case

$$A = \frac{3}{2} = a^2 \sin^2 \theta + b^2 \cos^2 \theta \quad (3.10)$$

$$B = -1 = 2(b^2 - a^2) \sin \theta \cos \theta \quad (3.11)$$

$$C = 1 = a^2 \cos^2 \theta + b^2 \sin^2 \theta \quad (3.12)$$

$$F = c = -a^2 b^2 \quad (3.13)$$

This system of equations can be solved for a, b, θ . For a constant c :

$$a^2 = \frac{-c}{b^2} \quad (3.14)$$

$$b^2 = \frac{-\frac{3}{2} \pm \sqrt{\frac{9}{4} + 4\cos^2\theta\sin^2\theta}}{2\cos^2\theta} \quad (3.15)$$

$$\sin(2\theta) = \frac{-1}{b(\theta)^2 + \frac{c}{b(\theta)}} \quad (3.16)$$

Once this system of equations is solved, the semi-major axis is given by a , the semi-minor axis is given by b , the angle of the semi-major axis is given by θ , and the angle of the semi-minor axis is given by $\theta + \frac{\pi}{2}$. The ellipse described above can be seen in the contour plot of V .

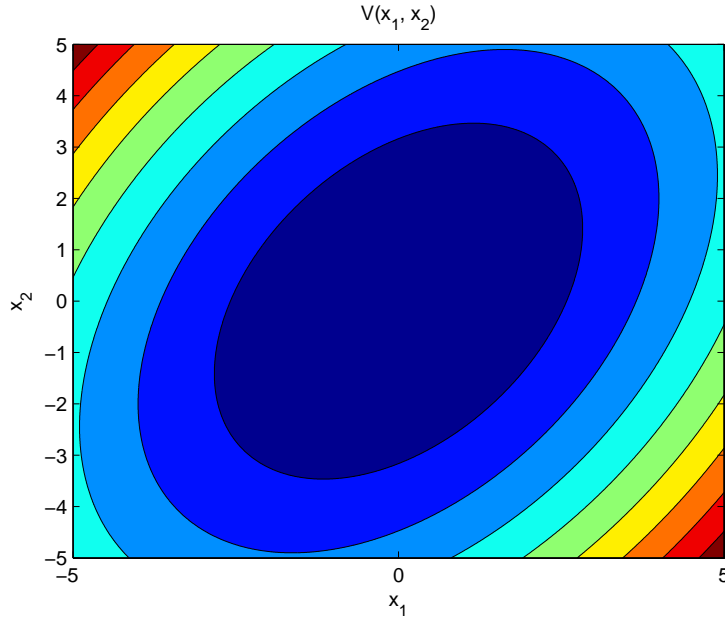

Figure 3.1: Contour plot of V . The sublevel set of V is anything inside a given contour corresponding to the constant c .

(d) The region of attraction (ROA) for V is bounded by trajectories. This region is described by the largest sublevel set in which V always remains. A conservative estimate of this region of attraction is given by the ellipse found when $a = 4, b = 1/4, \theta = 0$. This region can be expanded out to the trajectories given as the limits of the domain D . A larger estimate of the ROA is given by the largest subset of V for which \dot{V} remains negative. This is true for the ellipse at $\theta = 1.02, a = 5/3, b = 1$. This ellipse is shown in the image below.

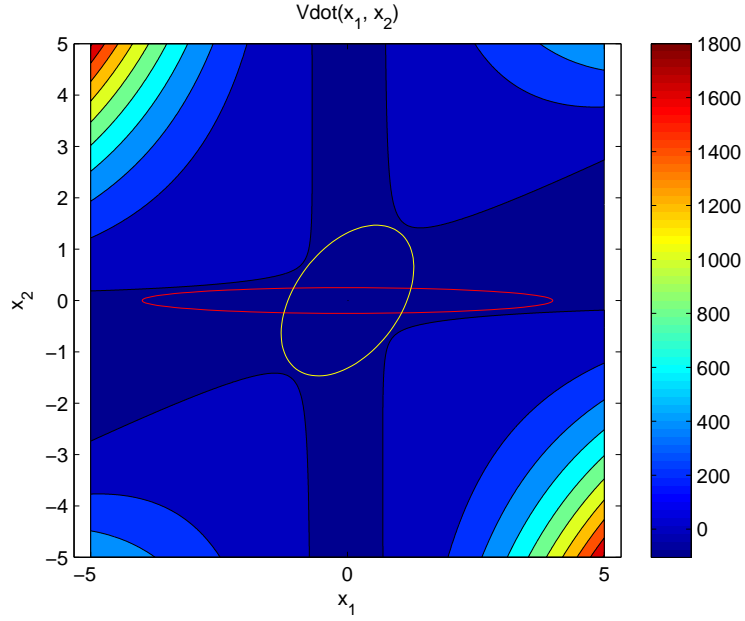

Figure 3.2: Estimates of the region of attraction plotted over a contour plot of \dot{V}

4 PROBLEM 4

a) Show that V is positive definite and decrescent for the given time-varying system:

$$V(t, x_1, x_2) = \frac{1}{2}(x_1 + x_2)^2 + \frac{1}{2}(1 + b(t))x_1^2 \quad (4.1)$$

$$\geq \begin{bmatrix} x_1 & x_2 \end{bmatrix} \begin{bmatrix} 2 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} x_1 & x_2 \end{bmatrix}^T = W_1(x) \quad (4.2)$$

Since $W_1(x)$ is p.d., and $V \geq W_1(x) \forall t$, V must be p.d. Also,

$$V(t, x_1, x_2) = \frac{1}{2}(x_1 + x_2)^2 + \frac{1}{2}(1 + b(t))x_1^2 \quad (4.3)$$

$$\leq \begin{bmatrix} x_1 & x_2 \end{bmatrix} \begin{bmatrix} 3 & \frac{1}{2} \\ \frac{1}{2} & 1 \end{bmatrix} \begin{bmatrix} x_1 & x_2 \end{bmatrix}^T = W_2(x) \quad (4.4)$$

Since $W_2(x)$ is p.d. and $V \leq W_2(x) \forall t$, V must be decrescent.

b) Show that the origin is globally asymptotically stable, and find the constants of the exponential bound:

First, we have already found that V is positive definite and decrescent. Additionally,

because $V \rightarrow \infty \Rightarrow x \rightarrow \infty$, V is radially unbounded. These properties hold for $D = \mathbb{R}^2$.

$$\dot{V} = \frac{\partial V}{\partial x_1} \dot{x}_1 + \frac{\partial V}{\partial x_2} \dot{x}_2 \quad (4.5)$$

$$= (4x_1 + x_2)\dot{x}_1 + (x_1 + x_2)\dot{x}_2 \quad (4.6)$$

$$= -2x_1^2 + (2 - b(t))x_1x_2 - (b(t) - 1)x_2^2 \quad (4.7)$$

$$\leq -2x_1^2 - 2x_1x_2 - 3x_2^2 \quad (4.8)$$

$$\leq -3\|x\| \quad (4.9)$$

Therefore, V is negative definite. This holds for $D = \mathbb{R}^2$, so the equilibrium is globally exponentially stable and bounded by $\|x\| \leq 3\|x_0\|\exp[-(t - t_0)]$. The constants for the exponential bound are found by

$$W_1(x) = \frac{1}{2}\|x\| \quad (4.10)$$

$$W_2(x) = \frac{3}{2}\|x\| \quad (4.11)$$

$$W_3(x) = -3\|x\| \quad (4.12)$$

$$k = \frac{k_2}{k_1} = 3 \quad (4.13)$$

$$\gamma = \frac{-k_3}{2k_2} = 1 \quad (4.14)$$

5 PROBLEM 5
